Construction annotation guide

Status of this guide

This release guide documents the intended label schema. It does not reconstruct every historical annotation decision or establish annotator independence. The original query-annotation guide is retained under docs/archive.

Track assignment

Assign U when the entity, competition/time frame, and requested statistic are sufficiently specified to determine a target. Assign C when a conventional frame can resolve ambiguity and should be disclosed. Assign X when essential omissions lead to materially different answers and a defensible default is unavailable. Record uncertainty rather than forcing agreement from the authored draft label.

Specification fields

Record entity, temporal, domain, intent, and methodology specification separately. The primary ambiguity source identifies the main omission; fine-grained labels need not agree simply because the track agrees. Use the supplied schema and codebook values, preserving the distinction between specified, underspecified, ambiguous, and conventional-assumption labels where present.

Clarification and interpretation

Record preferred action and clarification requirement. A useful clarification question targets the missing entity, time window, competition, or statistic. Cooperative interpretation examples are possible frames rather than a unique factual gold. Disclose alternatives and the criteria used to decide whether a default is defensible.

Data privilege

Structural, value, and container references are screened to avoid requiring the user to know internal representation identifiers. This is a design choice. No with-filter/without-filter experiment is included, so improved realism or performance is not an empirical finding.

Disagreements and release records

Keep A and B source values. Final labels in this release are the supplied final decisions; the export is not a dated adjudication log. Do not retrospectively invent reasons or timestamps. The original master remains historical and unfinished, with its open disputes preserved.

Agreement and construct validity

Recorded track agreement is 354/360, primary ambiguity-source agreement 253/360, and entity-specification agreement 166/360. High agreement on intentionally constructed tracks does not establish separability for naturally occurring requests.
